Introducing the Two-Sample t-Test

MOTIVATING THE TWO-SAMPLE T-TEST

An Important Data Science Question

Is group A different from group B in expectation?

Examples:

- Are customers who get a birthday gift less likely to leave than those who don't?
- Do patients who take Vitamin W get over the flu faster than patients who don't?
- Do democracies or autocracies start more wars?

In important Data Science Question

amples:

Are customers who get a birthday gift less likely to
leave than those who dont?

Do patients who take Vitanin W get over the flu
frater than patients who dont?

Do democracies or autocracies start more wars?

- 1. The two-sample t-test is one of the most common procedures in inferential statistics. What is it for? As a data scientist you will often face a question about two groups group A and group B. Someone will ask you if one is greater or less than than the other.
- 2. Questions like this are everywhere. In business, you have A-B testing.
- 3. In medicine, you may want to test a group of patients

5. What do these questions have in common? They all have

- taking a vitamin against a control group
 4. In political science, you may want to test whether
- democracies or autocracies start more wars.

- 1. Here's a specific example, with data.
- 2. write on slide: 13.3-12.1 = 1.2 outfits
- 3. Is this a big difference? is it just noise?
- 4. To be more precise, is this evidence that SF'ans have more black outfits than NYers in general?
- 5. To analyze this question, we need a model...

Two-Sample Model Framework

Basic Model Setup

Suppose $(X_1,..,X_{n_1})$ are i.i.d. with mean μ_X .

Suppose $(Y_1, ..., Y_{n_2})$ are i.i.d. with mean μ_Y .

Null Hypothesis

 H_0 : $\mu_X = \mu_Y$ (The two population means are equal)

Alternative hypotheses

 $H_1: \mu_X \neq \mu_Y$ (best choice in most cases)

 $H_2: \mu_X > \mu_Y$ $H_3: \mu_X < \mu_Y$ 2022-02-18

Hypothesis Testing

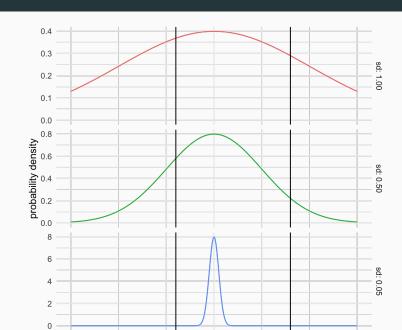

-Introducing the Two-Sample t-Test

└─Two-Sample Model Framework

- 1. A model is a representation of the world built of RVs. for a two-sample t-test, the model begins like this.
- 2. Let $X_1...X_{n_1}$ be RVs representing group A. Similarly for Y.
- 3. Let's assume that the X's are iid with mean μ_{X} . same for Y
- 4. We'll need more assumptions, but this is a start.
- 5. The null is that our two means are the same.
- 6. Our usual alternative is that the means are different.
- 7. It is also possible to run a one-sided test in special circumstances. alt is one mean is greater than other.
- 8. Given this model, how plausible is the null hypothesis?

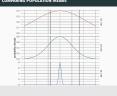

COMPARING POPULATION MEANS

Hypothesis Testing

-Introducing the Two-Sample t-Test

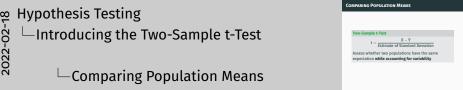

- 1. One important piece of information is how much does the number of black outfits vary in the population.
- 2. Here's a picture with three different distributions for our sample averages.
- 3. The top distribution has very high standard deviation. You can see that it doesn't seem unusual to get two sample averages that are 1.2 outfits apart.
- 4. The middle distribution has medium deviation. Now it starts to look a little more surprising that our two sample averages were 1.2 apart.
- 5. The bottom distribution has low standard deviation. Now it seems quite unlikely to get two sample averages 1.2

COMPARING POPULATION MEANS

Two-Sample t-Test

$$t = \frac{\bar{X} - \bar{Y}}{\text{Estimate of Standard Deviation}}$$

Assess whether two populations have the same expectation while accounting for variability

 Putting these ideas together, we can make a statistic by taking the difference in sample averages, and dividing by an estimate of standard deviation - that's exactly the idea behind the two- sample t-test

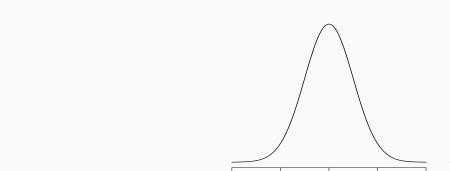

The Two-Sample z-Test

TWO-SAMPLE Z-TEST

Assumptions

Suppose $(X_1,..,X_{n_1})$ are i.i.d. with mean μ_X .

Suppose $(Y_1, ..., Y_{n_2})$ are i.i.d. with mean μ_Y . Assume $X \sim N(\mu_X, \sigma)$. $Y \sim N(\mu_Y, \sigma)$. We know σ .

Hypothesis Testing

└─The Two-Sample z-Test

└─Two-Sample *z-*Test

- 1. Before we tackle the two-sample t-test, let's begin with the simpler 2 samp. z test. unrealistic, but build intuition.
- 2. Same assumptions as before, but add assump. of equal var σ which we know.
- 3. How do we create a test statistic?

5. $V[\bar{X} - \bar{Y}] = V[\bar{X}] + V[\bar{Y}] = \sigma^2/n_1 + \sigma^2/n_2$

4. What is the distribution of $\bar{X} - \bar{Y}$? Let's use fact that a

- 6. $\bar{X} \bar{Y} \sim N(0, \sigma \sqrt{\frac{1}{n_1} + \frac{1}{n_2}})$ 7. Can use the standardized difference in means.
 - $z = \frac{\bar{X} \bar{Y}}{\sigma_{\sqrt{\frac{1}{n_a} + \frac{1}{n_a}}}} \sim N(0, 1)$
- 8. Here's the standard normal. As usual, we can create

1. Here's an exercise to build more intuition.

2.
$$Z = \frac{\bar{X} - \bar{Y}}{\sigma \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} = \frac{12.1 - 13.3}{2\sqrt{\frac{1}{50} + \frac{1}{50}}} = \frac{-1.2}{2\sqrt{\frac{1}{25}}} = -3.0$$

3. $Z > 1.96$ REJECT

4. We can also compute p-value 2*pnorm(-3) = .0027

GENERAL PROCEDURE FOR TESTING

Three steps:

- 1. Specify model and null hypothesis
- 2. Calculate z or t statistic
- 3. Plot statistic on the null distribution to get the p value.

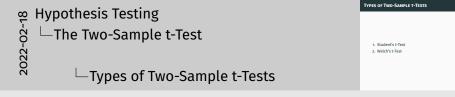

1. From this example, I hope you see that the two-sample t-test is not all that different from the one-sample tests we did earlier.

-General Procedure for Testing

2. No matter what the test is, there's a general pattern that you follow...

The Two-Sample t-Test

- 2. Welch's t-Test

- 1. There are actually two versions of the two-sample t test you should be aware of.
- 2. Student's t-test is the original t-test. it's simpler, but requires strong assumptions
- 3. Welch's t-test is more general, and this is really the modern t-test.

$$t = \frac{\bar{X} - \bar{Y}}{s\sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

$$s = \sqrt{\left(\frac{(n_1 - 1)s_{\chi}^2 + (n_2 - 1)s_{\gamma}^2}{n_1 + n_2 - 2}\right)}$$

Result

t has a T distribution with $n_1 + n_2 - 2$ degrees of freedom.

Your main goal is to explain to your audience why they should or should not care about the effect.

Three common effect size measures:

COHEN'S D

Cohen's d

Cohen's d is a measure of difference of means standardized by the variance in the data.

$$\frac{\overline{X}_A - \overline{X}_B}{s}$$

Where s is a pooled standard deviation: $\sqrt{\frac{(n_1-1)s_1^2+(n_2-1)s_2^2}{n_1+n_2}}$

- Answers the question "How many standard deviations apart are the groups?"
- The difference in sarcasm score between frequentists and Bayesians is d = 0.54 standard deviations.

Introduction to Non-parametric Tests

Non-parametric Tests

- t-test is parametric, like all the tests we've seen so far
 - Assumes the population comes from a parametric family of distributions
 - Typically the normal curves
- It is not always possible to meet this assumption
